

CLADDING THE MOST VITAL PART OF THE OVERALL DESIGN

A building façade system, predominantly at the front side of a building structure, is one of the most vital integral parts of a structure's overall design that adds unique characteristics to the building. Apart from the aesthetic value that it adds to the building, there are several other functional benefits of incorporating a façade into the building structure.

These systems protect the building against damage caused by high-speed winds and heavy rains, shielding the structure from extreme temperatures and humidity levels.

Often referred to as the external skin of the building, a façade provides protection from light penetration and offers natural ventilation.
